Title : The Effect of Heteroauxine on the Seedlings of the Scotch and Austrian Pines.

Orig Pub : Rev. padurilor, 1956, 71, No 3, 177-179

Abstract : Six day old seedlings of *Pinus silvestris* were subjected to a 48 hour treatment with solutions of heteroauxine in the following concentrations: 0.2, 0.1, 0.05, 0.02 and 0.01%. It was found that only in the variant having the 0.01% concentration of heteroauxine was there no plant loss. This indicates that the concentration specified is the closest to the maximum allowing viability in the seedling sprouts. In repeated tests with sprouts of *P. silvestris* and *P. nigra* the treatment with heteroauxine concentrations of 0.02-0.002% lasted 5 hours.

Abs Jour : Ref Zhur - Biol., No 5, 1958, 20159

It turned out that the cotyledons of *P. nigra* shoots developed best in concentrations of from 0.008 to 0.002%. The stems of the treated plants developed more weakly than those of the control. The roots of the treated plants (independently of the concentrations of solution) were considerably shorter, although thicker and stronger than the control. In *P. silvestris* the cotyledons of the treated specimens in the majority of cases developed better than the controls (especially in a concentration of 0.008%). The growth of the stems was weaker than in the control, and the roots, although shorter than the control, were considerably stronger.

TITLE: Chromatometric determination of anthranilic acid by total wet oxidation according to an equivalent weight ratio of 1 : 28

SOURCE: Acta chimica academiae scientiarum Hungaricae, v. 44, no. 3, 1965, 267-276

TOPIC TAGS: organometallic compound, chromate

ABSTRACT: As seen by the experimental results, anthranilic acid undergoes oxidation with sodium dichromate, in a medium of concentrated sulfuric acid at 115° within 40 minutes, in a stoichiometric reaction with the formation of water, carbon dioxide and ammonia. The mixture used for the moist combustion can also be used as a standard solution. When the solution is diluted at the end of the reaction, the excess chromium(VI) in it can be titrated with iron(II) in the presence of ferroin as indicator. When an 0.5 per cent correction is applied for the spontaneous decomposition of chromium(VI) solution not consumed in the oxidation, the titration values for anthranilic acid and for metal anthranilates agree within ± 0.2 per cent. One ml of 0.1 N sodium dichromate corresponds to 0.4898 mg of anthranilic acid or $M/650$ mg of divalent metals.

*M = molecular wt. The authors thank Professor, Doctor B. Lengyel for his participation in the experimental work. Orig. art. has: 1 figure and 6 tables. [Based on authors' Eng. abst.] [JPRS: 33,540]

TITLE: Second Conference on Grinding and Polishing of Glass ^{III}

PERIODICAL: Silikáty, 1960, Nr 2, p 213

ABSTRACT: This conference was held in Jablonec n. Nisou on September 22-25, 1959. Among the 150 participants were Dr A.F.Fedoseyev, Professor, Vice-President of the Institute for Silicate Chemistry of the Soviet Academy of Sciences, P.Ya.Bokin, Candidate of Technical Sciences (USSR) and Dr A. Kaller (Jena, East Germany). 19 Papers were read: P.Ya.Bokin (USSR) read a paper on the development of the theory of glass grinding in the USSR; A.Kaller read a paper on the relation between some physical properties of iron oxides and their polishing effects; J.Korelova read a paper on the development of the theory of glass polishing; A.S.Totes (USSR) read a paper on intensifying the process of glass polishing; S.Minař (Přerov) read a paper on the importance of physical and chemical factors during polishing of silicate glass which was the most valuable Czech contribution on theoretical research; J.Voldan read a paper on the effect

TITLE: Effect of the mechanical, thermal and chemical treatment of glass on its strength and surface quality

SOURCE: Sklar a keramik, no. 11, 1965, 336-338

TOPIC TAGS: ~~glussxpraduaty~~ glass manufacturing machinery, glass, glass property, mechanical property

ABSTRACT: The article reports on the investigation of the effect of the mechanical working of glass on its strength, and the effect of surface quality on strength in relation to the method of production and subsequent treatment. The study was undertaken because the effect of the mechanical working of glass on its strength has not been sufficiently investigated. The strength of the glass samples was determined by a method developed at the A. F. Yoffe Leningrad Physical Technical Institute of the AS USSR (Fizikotekhnicheskii Institut im. A. F. Yoffe AN SSSR) in which the samples are subject to increasing loads on a circular test block until they break. In every case at least 10 glass samples were tested. The average departure from the mean

Card 1/2

L 08669-67

ACC NR: AP6009564

value for strength was 15%, and the maximum departure 60% which does not exceed the limits of accuracy of the method. It was determined that a flame polished flat glass surface made with a Fourcault apparatus has a characteristic structure which can be made visible by 3 min etching in a 4% solution of HF. Mechanically polished glass which has also been treated by tempering or etching as in the case of flame polished glass, has the same or greater strength than flame polished glass. Orig. art has: 5 figures and 2 tables.

TITLE: Effect of composition and various physicochemical properties of glass on the productivity of grinding and polishing processes

SOURCE: Sklar i keramik, no. 12, 1965, 370-373

TOPIC TAGS: silicate glass, hardness, grinding, chemical stability, *GLASS PROPERTY*

ABSTRACT: The authors study the effect of glass composition on its grinding strength, microhardness, microstrength, elasticity and chemical stability, and also investigate the grinding strength as a function of changes in these properties. Specimens of glass in the $R_2O-RO-4SiO_2$ system were founded from chemically pure materials and silica sand in quartz crucibles at 1400-1450°C. The analytical compositions of the various types of glass are tabulated. The alkali components were lithium, sodium and potassium, while the metals used in the RO component were Mg, Ca, Zn, Sr, Cd, Ba, Pb and Be. Some types of commercial glass were also studied: quartz, borosilicate, barium crown and flint glass. Synthetic corundum was used for grinding the specimens after which they were polished with colcothar. The methods and equipment used for the measure-
